0.1 Major failure definition

In Project Charter, it has been stated that a major failure can be defined as the loss of a client's satellite coverage because of a failure in the network. However, this definition is not enough precise. For example, during a communication, it can happen that a data packet is lost, or has an error and it is discarded. This means that, for that packet, the communication was lost, but it does not mean that the communication with the client was lost. Another aspect to take into account is that a satellite may fail, but an alternative path can still exist and, therefore, the communication can continue. Moreover, if the client satellite loses all communication with all satellites in range, due to the different orbital velocities of the client satellite and the network satellites, the client satellite will eventually be in range of a functional network satellite.

For all these reasons, a more specific criteria is needed. In Project Charter it has also been stated that the network will provide communication between a client satellite and a ground station with a latency lower than 5 minutes (300 seconds, or 300,000 milliseconds). A major failure will consist in a failure in the network that causes a message to arrive from a client satellite to a client ground station with more than 5 minutes of delay, or not arrive at all. Derived from this definition, a minor failure can also be defined. It can be defined as a delay of more than 5 minutes in a communication between a client satellite and a ground station without any failure in the network.

0.1.1 Major failure

Because of the different height of the client satellite and the network satellites, if all the network satellites are out of range of the client satellite, the client satellite may come in range of a working network satellite if enough time passes. In some cases, this can happen in less than 5 minutes and, therefore, it will not be considered a major failure. For this reason, a more critical situation will be considered. It will be considered that the client satellite moves at the same speed as the network satellites, in the same orbital plane. In this situation, a major failure can happen because for three reasons: all network satellites in range of the client satellite fail, all ground stations fail, or some satellites fail but the alternative path takes more than 5 minutes to transmit the information.

Satellite in range failure

The first reason will be evaluated in the following lines. Depending on the location of the satellite and the distribution of the satellites in the constellation, the number of adjacent satellites may vary. A satellite over the equator can have up to six adjacent satellites. If a client satellite only communicates with this network satellite, a major failure will be the failure of this satellite, as it can be seen in Figure 1. It can also be the failure of a group of satellites

surrounding the transmitting satellite, but this number is larger and, therefore, it would not be considered since the failure of the transmitting satellite is more restrictive.

Figure 1: Failure due to the loss of the only satellite in range of the client satellite.

However, it is rare for a client satellite to only have one network satellite in range. It would need to be very close to the network satellite orbit, or to have an antenna with very narrow radiation pattern. For antennas with almost half-spherical patterns (an angle of 10° over their horizontal plane has been considered as the minimum angle capable of receiving and transmitting), the minimum height over the satellite network in order to see more than one satellite is, approximately, 70 km, considering that our constellation is at 500 km height over the Earth's surface. This means that the majority of clients would have in range more than one satellite. For those clients, the critical failure would be similar as the ones in Figure 2 and Figure 3. In the case of client satellites within the 70 km distance, and because of the little distance between client and network satellite, it is strongly recommended the use of isotropic radiator antennas, which will allow to see more network satellites.

Figure 2: Failure due to the loss of all possible communication satellites if the client can communicate to three network satellites.

Figure 3: Failure due to the loss of all possible communication satellites if the client can communicate to seven network satellites.

As it can be seen, the critical failure depends on the communication range of the client satellite. Taking the more restrictive one would mean considering the failure of only one satellite. However, it has been stated that the use of isotropic radiation antennas is highly recommended for client satellites that are at less than 70 km from the network orbits. Therefore, this critical failure will not be considered. Instead, it will be considered the case of three network satellites. For a critical failure to happen, at least three adjacent satellites must fail. There is no time requirement for this criteria, since it does not matter at which time they fail, but the fact that the three of them are fallen at a given time.

Ground station failure

Since any satellite in the network is able to communicate with any ground station, in order to have a critical failure due to a ground station failure, all ground stations must fail. It will not be considered a failure the loss of connection to a ground station caused by bad weather conditions or radio-frequency interference, since it is not a failure in the network but an anomaly in the medium.

Therefore, for a critical failure caused by ground station failures to happen, all ground stations must fail. Since at least three ground stations will be used, the three of them must fail. As the previous case, the time of failure does not matter, but the fact that they remain unoperative at a given time.

Transmitting time failure

In the following lines, a major failure due to a delay superior to 5 minutes originated by a failure will be evaluated. First of all, it is needed to evaluate the transmission time. The minimum data rate that will handle the satellites is 25 Mbit/s. Therefore, it will be considered 25 Mbit/s as the data rate of the satellites, since it is the most restrictive. The protocols chosen, by default, cannot handle data units of more than 62,500 bytes, approximately. This is 500,000 bits. With the data rate chosen, the time to transmit this information is 0.02 seconds. For a path of 20 nodes, and considering that a satellite receives the entire packet before sending it again, the transmission time will be 0.4 seconds. The transmission is done using electromagnetic waves, which move at the speed of light. For this short distances, it can be considered to be

instantaneously. The time used to process each data packet has to be taken into account. If each node needs 1 second to process the packet, the total processing time will be 20 seconds.

Finally, the time to recognize a fallen satellite and the time to compute an alternative route is required. By default, OSPF protocol requires 40 seconds of no response to label an adjacent node as dead. When this time expires, the fallen link state will be transmitted. When a node receives this update, it will wait 5 seconds and then it will calculate new routes. If the process requires 100 seconds, the total time until a failure happens and a new route is calculated is 145 seconds. With the processing time of 20.4 seconds, if one node fails, the time to deliver the message is 165.4 seconds. But if another node fails while the message is still being delivered, the total time to deliver the message would be 310.4 seconds, which is superior to 5 minutes.

Therefore, for a critical failure to happen because of a delay of more than 5 minutes in the communication due to a failure in the network, two satellites must fail in less than 160 seconds, and both of them must be in a communication path between a client and a ground station.

Conclusion

It can be concluded that a major failure can happen due to various factors:

- The failure of at least three adjacent satellites.
- The failure of all ground stations. It would be at least 3 ground stations.
- The failure of at least two satellites in a communication route in less than 3 minutes.
